Summary

JVM backend engineer, nearly 4 years in production services and data-heavy pipelines. **Cut audience gathering from 6+ min to 1–10 s and export from 8 h to 15 min (>32x)**; targeting over **~30M transactions/day**. Stack: Java/Kotlin, Spring Boot, PostgreSQL, ClickHouse, Kafka, gRPC.

Core Skills

Languages: Java, Kotlin, Python (also Go, TypeScript, SQL)

Backend: Spring Boot, REST APIs, gRPC, microservices, API design, unit and integration testing, code review

Data & Messaging: PostgreSQL, ClickHouse/CHaaS, Redis, Kafka, Postgres-backed task queues, S3

Infrastructure: Docker, Kubernetes, nginx, GitLab CI/CD, monitoring (Prometheus, OpenTelemetry, Grafana)

Approaches: distributed systems, async orchestration, idempotency, load isolation, feature flags

Experience

Software Engineer (Backend) | T-Bank

Oct 2025 – Present

- Backend of a manager-facing cashback audience platform (Kotlin/Spring): managers build audiences for partner-funded campaigns; the system includes and excludes customers using transaction, customer, and partner data.
- Cut audience gathering from 6+ min (hours for large ones) to 1–10 s** and made it size-independent: reworked DAG structure, queue isolation, concurrency limits, and ClickHouse workload management. Owned the task from initiative to production rollout.
- Cut audience export from 8+ h to 15 min (>32x)**, eliminating the main bottleneck between audience gathering and partner platform delivery.
- Designed a control-plane/data-plane split: the Kotlin/Spring service kept business logic and lifecycle ownership, while heavy materialization and export moved to an internal Go backend via gRPC, ClickHouse, and S3. Contract-first async integration: typed errors, idempotency, cancellation/retry, feature flags, legacy fallback, and metrics.
- Built a quantitative latency model for the Postgres-backed DAG pipeline, decomposing total time into queue wait, execution, scheduler-polling gaps, and critical-path depth — which drove the optimizations above.
- Identified and adapted a reusable internal platform capability from another team: bucketized ClickHouse processing, CH-to-S3 streaming, task-type isolation, and bounded concurrency.
- Delivered spend/income targeting over **~30M transactions/day** and 1.5 years of history; estimated product impact **~\$600K/year**. Moving part of audience building to ClickHouse-as-a-Service made a critical scenario **~5x** faster.
- Accelerated the main CI pipeline by **5–7 min (15–20%)**, saved 40–60 manual hours/month by automating targeting flows; built AI-assisted tools for GitLab review, CI refactoring, and RAG onboarding.
- Fixed a production document-generation bug that emitted incorrect data, removing a recurring source of manual support follow-ups.

Backend and Automation Engineer | Freelance / Client Projects

May 2022 – Sep 2025

- Built a commercial real estate analytics platform combining auction data, CIAN listings, geocoding, a Telegram bot, an admin panel, and a searchable property catalog.
- Reduced property economics evaluation to ~10 min** and district-level market analysis to 7–10 min: realtors see price, yield, cash flow, payback, and comparables without manually cross-checking sources.
- Delivered booking, loyalty, and service-slot workflows: REST APIs, PostgreSQL, Redis, Telegram Mini Apps, Docker/nginx deployment, YClients integration, webhooks, and retries.
- Launched a service-business MVP with customer, partner, and admin flows (**3 onboarded partners**): slot vacancy down 35%, partner revenue up 20%, booking conversion up 25%.
- Implemented matching, Elo rating, bonus debit/credit settlement, contact-based registration, and role-aware flows for partner/customer products.

Education

Central University | B.Sc. in Computer Science | expected graduation: 2026

Additional: Harvard CS50, MIT OCW Algorithms, freeCodeCamp Java/Spring
